Acid Base Equilibria

Bronsted-Lowry Definition of acid Base behaviour

A **Bronsted-Lowry acid** is defined as a substance that can **donate a proton**.
A **Bronsted-Lowry base** is defined as a substance that can **accept a proton**.

$HCl (g) + H_2O (l) \rightarrow H_3O^+{}_{(aq)} + Cl^-{}_{(aq)}$

acid   base   acid   base
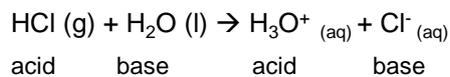

Each acid is linked to a conjugate base on the other side of the equation.

Calculating pH

$$pH = -log[H^+]$$

Where $[H^+]$ is the concentration of hydrogen ions in the solution.

Calculating pH of strong acids

Strong acids **completely dissociate**

The concentration of hydrogen ions in a monoprotic strong acid will be the same as the concentration of the acid.

For HCl and HNO_3 the $[H^+(aq)]$ will be the same as the original concentration of the acid.

For 0.1 mol dm^{-3} HCl the pH will be $-log[0.1] = 1.00$

Always give pH values to **2d.p**. In the exam

Finding [H⁺] from pH

$$[H^+] = 1 \times 10^{-pH}$$

On most calculators this is done by pressing

Inv (or 2nd function)$\rightarrow$ log $\rightarrow$ - number(pH)

Example 1
Calculate the concentration of HCl with a pH of 1.35
$[H^+] = 1 \times 10^{-1.35} = 0.045$ mol dm^{-3}

Ionic Product for water

In all aqueous solutions and pure water the following equilibrium occurs: $H_2O (l) \rightleftharpoons H^+{}_{(aq)} + OH^-{}_{(aq)}$

This equilibrium has the following equilibrium expression

$$Kc = \frac{[H^+{}_{(aq)}][OH^-{}_{(aq)}]}{[H_2O(l)]} \rightarrow$$

Rearrange to

$Kc \times [H_2O (l)] = [H^+{}_{(aq)}][OH^-{}_{(aq)}] \longrightarrow$

Because $[H_2O (l)]$ is much bigger than the concentrations of the ions, we assume its value is constant and make a new constant Kw

$$Kw = [H^+{}_{(aq)}][OH^-{}_{(aq)}]$$

Learn this expression

At 25ºC the value of Kw for all aqueous solutions is 1×10^{-14} mol^{2}dm^{-6}

The Kw expression can be used to calculate $[H^{+}{}_{(aq)}]$ ions if we know the $[OH^-{}_{(aq)}]$ ions and vice versa.

Finding pH of pure water

Pure water/ neutral solutions are **neutral** because the $[H^+{}_{(aq)}] = [OH^-{}_{(aq)}]$
Using $Kw = [H^+{}_{(aq)}][OH^-{}_{(aq)}]$ then when neutral $Kw = [H^+{}_{(aq)}]^2$
and $[H^+{}_{(aq)}] = \sqrt{Kw}$
At 25ºC $[H^+{}_{(aq)}] = \sqrt{1 \times 10^{-14}} = 1 \times 10^{-7}$ so pH = 7

Example 2 : Calculate the pH of water at 50ºC given that $K_w = 5.476 \times 10^{-14}$ mol^2 dm^{-6} at 50ºC
$[H^+{}_{(aq)}] = \sqrt{Kw} = \sqrt{5.476 \times 10^{-14}} = 2.34 \times 10^{-7}$ mol dm^{-3}
pH = - log 2.34×10^{-7} = **6.6**
It is still neutral though as $[H^+{}_{(aq)}] = [OH^-{}_{(aq)}]$

At different temperatures to 25ºC the pH of pure water changes. Le Chatelier's principle can predict the change. The dissociation of water is endothermic so increasing the temperature would push the equilibrium to the right giving a bigger concentration of H^+ ions and a lower pH.

Calculating pH of a Strong Base

For bases we are normally given the concentration of the hydroxide ion.

To work out the pH we need to work out $[H^+(aq)]$ using the Kw expression.

Strong bases completely dissociate into their ions.
$NaOH \rightarrow Na^+ + OH^-$

Example 3:

Calculate the pH of the strong base 0.1 mol dm^{-3} NaOH

Assume complete dissociation.

$Kw = [H^{+ (aq)}][OH^{- (aq)}] = 1 \times 10^{-14}$

$[H^+(aq)] = Kw/ [OH^{- (aq)}] = 1 \times 10^{-14} / 0.1 = 1 \times 10^{-13}$ M

$pH = -\log[1 \times 10^{-13}] = \mathbf{13.00}$

Weak Acids

Weak acids only **slightly dissociate** when dissolved in water, giving an equilibrium mixture.

$HA + H_2O (l) \rightleftharpoons H_3O^+ {}_{(aq)} + A^- {}_{(aq)}$ We can simplify this to $\longrightarrow$ $HA {}_{(aq)} \rightleftharpoons H^+ {}_{(aq)} + A^- {}_{(aq)}$
Weak acids dissociation expression

$$Ka = \frac{[H^+ {}_{(aq)}][A^- {}_{(aq)}]}{[HA (aq)]}$$

The K_a for ethanoic acid is 1.7×10^{-5} mol dm^{-3}.

The larger ka the stronger the acid.

Example 4 Write an equation for dissociation of propanoic acid and its Ka expression

$CH_3CH_2CO_2H_{(aq)} \rightleftharpoons H^+ {}_{(aq)} + CH_3CH_2CO_2^- {}_{(aq)}$
$$Ka = \frac{[H^+ {}_{(aq)}][CH_3CH_2CO_2^- {}_{(aq)}]}{[CH_3CH_2CO_2H_{(aq)}]}$$

pKa
Sometimes Ka values are quoted as pKa values
$pKa = -\log Ka$ so $Ka = 10^{-pKa}$

Calculating pH of a Weak Acid

To make the calculation easier two assumptions are made to simplify the Ka expression:

1) $[H^+ {}_{(aq)}]_{eqm} = [A^- {}_{(aq)}]_{eqm}$ because they have dissociated according to a 1:1 ratio.

2) As the amount of dissociation is small we assume that the initial concentration of the undissociated acid has remained constant.

So $[HA {}_{(aq)}]_{eqm} = [HA_{(aq)}]_{initial}$

$$Ka = \frac{[H^+ {}_{(aq)}][A^- {}_{(aq)}]}{[HA (aq)]}$$

Simplifies to $\downarrow$

$$Ka = \frac{[H^+ {}_{(aq)}]^2}{[HA {}_{(aq)}]_{initial}}$$

Example 5 What is the pH of a solution of 0.01 mol dm^{-3} ethanoic acid (ka is 1.7×10^{-5} mol dm^{-3})?

$CH_3CO_2H_{(aq)} \rightleftharpoons H^+ {}_{(aq)} + CH_3CO_2^- {}_{(aq)}$
$$Ka = \frac{[H^+ {}_{(aq)}][CH_3CO_2^- {}_{(aq)}]}{[CH_3CO_2H_{(aq)}]} \longrightarrow Ka = \frac{[H^+ {}_{(aq)}]^2}{[CH_3CO_2H_{(aq)}]_{initial}} \rightarrow 1.7 \times 10^{-5} = \frac{[H^+ {}_{(aq)}]^2}{0.01}$$

$[H^+ {}_{(aq)}]^2 = 1.7 \times 10^{-5} \times 0.01$

$[H^+ {}_{(aq)}] = \sqrt{1.7 \times 10^{-7}} = 4.12 \times 10^{-4}$

$pH = -\log [H^+] = -\log (4.12 \times 10^{-4})$

$pH = 3.38$

Example 6 Calculate the concentration of propanoic acid with a pH of 3.52 (ka is 1.35×10^{-5} mol dm^{-3})

$CH_3CH_2CO_2H_{(aq)} \rightleftharpoons H^+ {}_{(aq)} + CH_3CH_2CO_2^- {}_{(aq)}$
$[H^+] = 1 \times 10^{-3.52} = 0.000302$M

$$Ka = \frac{[H^+ {}_{(aq)}][CH_3CH_2CO_2^- {}_{(aq)}]}{[CH_3CH_2CO_2H_{(aq)}]} \longrightarrow Ka = \frac{[H^+ {}_{(aq)}]^2}{[CH_3CH_2CO_2H_{(aq)}]_{initial}} \rightarrow 1.35 \times 10^{-5} = \frac{[0.000302]^2}{[CH_3CH_2CO_2H_{(aq)}]_{initial}}$$

$[CH_3CH_2CO_2H_{(aq)}] = 9.12 \times 10^{-8} /1.35 \times 10^{-5}$ $[CH_3CH_2CO_2H_{(aq)}] = 6.75 \times 10^{-3}$ mol dm^{-3}

pH Calculations involving Neutralisation Reactions

These can be quite complex calculations working out the pH of a partially neutralised acid or the pH of the solution if too much alkali has been added and has gone past neutralisation. The method differs if the acid is strong or weak for the partially neutralised case.

Strong Acid and Strong Base Neutralisations

Work out moles of original acid
and hence moles H^+
Work out moles of base added
and hence moles OH^-
Work out which one is in excess

If excess acid →
Work out new concentration of excess H^+ ions
$$[H^+] = \frac{\text{moles excess } H^+}{\text{total volume (dm}^3)}$$

$$pH = -\log [H^+]$$

Total volume = vol of acid + vol of base added

If excess alkali →

Work out new concentration of excess OH^- ions
$$[OH^-] = \frac{\text{moles excess } OH^-}{\text{total volume (dm}^3)}$$

$$[H^+] = K_w/[OH^-]$$

$$pH = -\log [H^+]$$

Total volume = vol of acid + vol of base added

Example 7 $15cm^3$ of 0.5 mol dm^{-3} HCl is reacted with $35cm^3$ of 0.55 mol dm^{-3} NaOH. Calculate the pH of the resulting mixture.

Moles HCl =mol H^+ = conc x vol = 0.5 x 0.015 = 0.0075mol
Moles NaOH =mol OH^- = conc x vol = 0.55 x 0.035 = 0.01925
$H^+ + OH^- \rightarrow H_2O$
Moles of OH^- in excess = 0.01925 – 0.0075= 0.01175
$$[OH^-] = \frac{\text{moles excess } OH^-}{\text{total volume (dm}^3)}$$
$$= 0.01175/ 0.05 = 0.235 \text{ mol dm}^{-3}$$

$$[H^+] = K_w/[OH^-]$$
$$= 1 \times 10^{-14} / 0.235 = 4.25 \times 10^{-14}$$
$$pH = -\log [H^+]$$
$$= -\log 4.25 \times 10^{-14}$$
$$= 13.37$$

Example 8 $45cm^3$ of 1 mol dm^{-3} HCl is reacted with $30cm^3$ of 0.65 mol dm^{-3} NaOH. Calculate the pH of the resulting mixture.

Moles HCl =mol H^+ = conc x vol = 1 x 0.045 = 0.045mol
Moles NaOH =mol OH^- = conc x vol = 0.65 x 0.030 = 0.0195
$H^+ + OH^- \rightarrow H_2O$
Moles of H^+ in excess = 0.045-0.0195 = 0.0255
$$[H^+] = \frac{\text{moles excess } H^+}{\text{total volume (dm}^3)}$$
$$= 0.0255/ 0.075 = 0.34 \text{ mol dm}^{-3}$$
$$pH = -\log [H^+]$$
$$= -\log 0.34$$
$$= 0.47$$

Strong diprotic acids and bases

Questions of the type in Example 7 and 8 may include strong diprotic acids such as H_2SO_4 or bases such as $Ba(OH)_2$.

Example 9 $35cm^3$ of 0.5 mol dm^{-3} **H_2SO_4** is reacted with $30cm^3$ of 0.55 mol dm^{-3} NaOH. Calculate the pH of the resulting mixture.

Moles **H_2SO_4** = conc x vol = 0.5 x 0.035 = 0.0175mol

Moles H^+ = 0.0175 x2 = 0.035
Moles NaOH =mol OH^- = conc x vol = 0.55 x 0.030 = 0.0165
$H^+ + OH^- \rightarrow H_2O$
Moles of H^+ in excess = 0.035 -0.0165 = 0.0185
$$[H^+] = \frac{\text{moles excess } H^+}{\text{total volume (dm}^3)}$$

$$= 0.0185/ 0.065 = 0.28 \text{ mol dm}^{-3}$$

$$pH = -\log [H^+]$$
$$= -\log 0.28$$
$$= 0.55$$

Example 10 $15cm^3$ of 0.5mol dm^{-3} HCl is reacted with $35cm^3$ of 0.45 mol dm^{-3} **$Ba(OH)_2$**. Calculate the pH of the resulting mixture.

Moles HCl = mol H^+ = conc x vol = 0.5 x 0.015 = 0.0075mol

Moles **$Ba(OH)_2$** = conc x vol = 0.45 x 0.035 = 0.01575

Moles OH^- = 0.01575 x2 = 0.0315
$H^+ + OH^- \rightarrow H_2O$
Moles of OH^- in excess = 0.0315 – 0.0075= 0.024
$$[OH^-] = \frac{\text{moles excess } OH^-}{\text{total volume (dm}^3)}$$

$$= 0.024/ 0.05 = 0.48 \text{ mol dm}^{-3}$$

$$[H^+] = K_w/[OH^-]$$
$$= 1 \times 10^{-14} / 0.48 = 2.08 \times 10^{-14}$$
$$pH = -\log [H^+]$$
$$= -\log 2.08 \times 10^{-14}$$
$$= 13.68$$

Weak Acid and Strong Base Neutralisations

Work out moles of original acid
Work out moles of base added
Work out which one is in excess

If excess alkali use the same method with excess alkali and strong acid above

If excess acid →

Work out new concentration of excess HA

$$[HA] = \frac{\text{initial moles HA} - \text{moles OH}^-}{\text{total volume (dm}^3)}$$

Work out concentration of salt formed $[A^-]$

$$[A^-] = \frac{\text{moles OH}^- \text{ added}}{\text{total volume (dm}^3)}$$

Rearrange $ka = \frac{[H^+][A^-]}{[HA]}$ to get $[H^+]$

$$pH = -\log[H^+]$$

Example 11 55cm³ of 0.5 mol dm⁻³ CH_3CO_2H is reacted with 25cm³ of 0.35 mol dm⁻³ NaOH. Calculate the pH of the resulting mixture?

$$CH_3CO_2H + NaOH \rightarrow CH_3CO_2Na + H_2O$$

ka is 1.7×10^{-5} mol dm⁻³

Moles CH_3CO_2H = conc x vol = 0.5 x 0.055 = 0.0275mol
Moles NaOH = conc x vol = 0.35 x 0.025 = 0.00875

Moles of CH_3CO_2H in excess = 0.0275 - 0.00875 = 0.01875 (as 1:1 ratio)

$$[CH_3CO_2H] = \frac{\text{moles excess } CH_3CO_2H}{\text{total volume (dm}^3)}$$

$$= 0.01875 / 0.08 = 0.234M$$

$$[CH_3CO_2^-] = \frac{\text{moles OH}^- \text{ added}}{\text{total volume (dm}^3)}$$

$$= 0.00875 / 0.08 = 0.109M$$

$$ka = \frac{[H^+][CH_3CO_2^-]}{[CH_3CO_2H]}$$

$[H^+] = ka \times [CH_3CO_2H] / [CH_3CO_2^-]$

$= 1.7 \times 10^{-5} \times 0.234 / 0.109$

$= 3.64 \times 10^{-5}$

$pH = -\log[H^+]$

$= -\log 3.64 \times 10^{-5}$

$= 4.44$

Working out pH of a weak acid at half equivalence

When a weak acid has been reacted **with exactly half the neutralisation volume of alkali**, the above calculation can be simplified considerably.

$$ka = \frac{[H^+][CH_3CO_2^-]}{[CH_3CO_2H]}$$

At half neutralisation we can make the assumption that [HA] = [A-]

So $[H^+_{(aq)}] = ka$ And **pH = pka**

Example 12

Calculate the pH of the resulting solution when **25cm³ of 0.1M** NaOH is added to **50cm³ of 0.1M** CH_3COOH (ka 1.7×10^{-5})

From the volumes and concentrations spot it is half neutralisation (or calculate)

pH = pka = -log (1.7×10^{-5}**) = 4.77**

Diluting an acid or alkali

pH of diluted strong acid

$$[H^+] = [H^+]_{old} \times \frac{\text{old volume}}{\text{new volume}}$$

$$pH = -\log[H^+]$$

pH of diluted base

$$[OH^-] = [OH^-]_{old} \times \frac{\text{old volume}}{\text{new volume}}$$

$$[H^+] = \frac{K_w}{[OH^-]}$$

$$pH = -\log[H^+]$$

Example 13 Calculate the new pH when 50.0 cm³ of 0.150 mol dm⁻³ HCl is mixed with 500 cm³ of water.

$$[H^+] = [H^+]_{old} \times \frac{\text{old volume}}{\text{new volume}}$$

$$[H^+_{(aq)}] = 0.150 \times \frac{0.05}{0.55}$$

$[H^+_{(aq)}] = 0.0136$

$pH = -\log[H^+]$

$= -\log 0.0136$

$= 1.87$

Buffer Solutions

A Buffer solution is one where the pH does **not change significantly** if **small** amounts of acid or alkali are added to it.

An **acidic** buffer solution is made from a **weak acid** and a **salt of that weak acid** (made from reacting the weak acid with a strong base).

Example : ethanoic acid and sodium ethanoate

$CH_3CO_2H_{(aq)}$ and $CH_3CO_2^- Na^+$
A **basic** buffer solution is made from a weak base and a salt of that weak base (made from reacting the weak base with a strong acid).

Example :ammonia and ammonium chloride NH_3 and $NH_4^+Cl^-$

How Buffer solutions work

In an ethanoic acid buffer

$CH_3CO_2H_{(aq)} \rightleftharpoons CH_3CO_2^-_{(aq)} + H^+_{(aq)}$

Acid   conjugate base
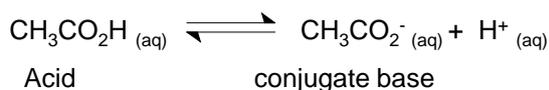

In a buffer solution there is a much higher concentration of the salt $CH_3CO_2^-$ ion than in the pure acid.

The buffer contains a reservoir of HA **and** A $^-$ ions

If **small amounts of acid is added** to the buffer: Then the above equilibrium will shift to the left removing nearly all the H^+ ions added,
$CH_3CO_2^-_{(aq)} + H^+_{(aq)} \rightarrow CH_3CO_2H_{(aq)}$

As there is a large concentration of the salt ion in the buffer the ratio $[CH_3CO_2H]/ [CH_3CO_2^-]$ stays almost constant, so the pH stays fairly constant.

$$[H^+_{(aq)}] = Ka \frac{[CH_3CO_2H_{(aq)}]}{[CH_3CO_2^-_{(aq)}]}$$

If **small amounts of alkali is added** to the buffer. The OH^- ions will react with H^+ ions to form water.

$H^+ + OH^- \rightarrow H_2O$
The Equilibrium will then shift to the right to produce more H^+ ions.

$CH_3CO_2H_{(aq)} \rightleftharpoons CH_3CO_2^-_{(aq)} + H^+_{(aq)}$

Some ethanoic acid molecules are changed to ethanoate ions but as there is a large concentration of the salt ion in the buffer the ratio $[CH_3CO_2H]/ [CH_3CO_2^-]$ stays almost constant, so the pH stays fairly constant.

Learn these explanations carefully and be able to write the equilibrium to illustrate your answer.

5

Calculating the pH of Buffer Solutions

We still use the weak acids dissociation expression

$$Ka = \frac{[H^+_{(aq)}][A^-_{(aq)}]}{[HA_{(aq)}]}$$

But here we assume the [A⁻] concentration is due to the added salt only

Normally we rearrange to →

$$[H^+_{(aq)}] = Ka \frac{[HA_{(aq)}]}{[A^-_{(aq)}]}$$

The salt content can be added in several ways: a salt solution could be added to the acid or some solid salt added. A buffer can also be made by partially neutralising a weak acid with alkali and therefore producing salt.

We also assume the Initial concentration of the acid has remained constant, because amount that has dissociated or reacted is small.

Example 14: making a buffer by adding a salt solution

Calculate the pH of a buffer made from 45cm³ of 0.1 mol dm⁻³ ethanoic acid and 50cm³ of 0.15 mol dm⁻³ sodium ethanoate (Ka = 1.7 x 10⁻⁵)

We can enter moles of acid and salt straight into the equation as they both have the same new final volume

Work out the moles of both solutions
Moles ethanoic = conc x vol = 0.1 x 0.045 = 0.0045mol
Moles sodium ethanoate = conc x vol = 0.15 x 0.050 = 0.0075

$$[H^+_{(aq)}] = Ka \frac{[HA_{(aq)}]}{[A^-_{(aq)}]}$$

$$[H^+_{(aq)}] = 1.7 \times 10^{-5} \times \frac{0.0045}{0.0075} \Rightarrow [H^+_{(aq)}] = 1.02 \times 10^{-5}$$

pH = − log [H⁺]
= -log 1.02x 10⁻⁵
= 4.99

Example 15 : making a buffer by adding a solid salt

A buffer solution is made by adding 1.1g of sodium ethanoate into 100 cm³ of 0.4 mol dm⁻³ ethanoic acid. Calculate its pH. (Ka =1.7 x10⁻⁵)

We can enter moles of acid and salt straight into the equation as they both have the same new final volume

Work out the moles of both solutions
Moles ethanoic = conc x vol = 0.4 x 0.1 = 0.04mol
Moles sodium ethanoate = mass/Mr= 1.1/82 = 0.0134

$$[H^+_{(aq)}] = Ka \frac{[HA_{(aq)}]}{[A^-_{(aq)}]}$$

$$[H^+_{(aq)}] = 1.7 \times 10^{-5} \times \frac{0.04}{0.0134} \Rightarrow [H^+_{(aq)}] = 5.07 \times 10^{-5}$$

pH = − log [H⁺]
= -log 5.07x 10⁻⁵
= 4.29

If a buffer is made by adding sodium hydroxide to partially neutralise a weak acid then follow the method below

---

Example 16 55cm³ of 0.5 mol dm⁻³ CH_3CO_2H is reacted with 25cm³ of 0.35 mol dm⁻³ NaOH. Calculate the pH of the resulting buffer solution.

$$CH_3CO_2H + NaOH \rightarrow CH_3CO_2Na + H_2O$$

ka is 1.7 x 10⁻⁵ mol dm⁻³

Moles CH_3CO_2H = conc x vol =0.5x 0.055 = 0.0275mol
Moles NaOH = conc x vol = 0.35 x 0.025 = 0.00875

Moles of CH_3CO_2H in excess = 0.0275-0.00875 = 0.01875 (as 1:1 ratio)

$$[CH_3CO_2H] = \frac{\text{moles excess } CH_3CO_2H}{\text{total volume (dm}^3)}$$

= 0.01875/ 0.08 = 0.234M

$$[CH_3CO_2^-] = \frac{\text{moles OH}^- \text{ added}}{\text{total volume (dm}^3)}$$

= 0.00875/ 0.08 = 0.109M

$$ka = \frac{[H^+][CH_3CO_2^-]}{[CH_3CO_2H]}$$

[H⁺] = ka x[CH_3CO_2H] / [$CH_3CO_2^-$]
= 1.7 x 10⁻⁵ x 0.234 / 0.109
= 3.64 x 10⁻⁵

pH = − log [H⁺]
= -log 3.64 x 10⁻⁵
= 4.44

Calculating change in pH of buffer on addition of small amount of acid or alkali

If a small amount of alkali is added to a buffer then the moles of the buffer acid would reduce by the number of moles of alkali added and the moles of salt would increase by the same amount so a new calculation of pH can be done with the new values.

$$CH_3CO_2H_{(aq)} + OH^- \rightarrow CH_3CO_2^-{}_{(aq)} + H_2O_{(l)}$$

If a small amount of acid is added to a buffer then the moles of the buffer salt would reduce by the number of moles of acid added and the moles of buffer acid would increase by the same amount so a new calculation of pH can be done with the new values.

$$CH_3CO_2^-{}_{(aq)} + H^+ \rightarrow CH_3CO_2H_{(aq)}$$
Example 17: 0.005 mol of NaOH is added to 500cm³ of a buffer where the concentration of ethanoic acid is 0.200 mol dm^{-3} and the concentration of sodium ethanoate is 0.250 mol dm^{-3} . (Ka = 1.7 x 10^{-5})

Calculate the pH of the buffer solution after the NaOH has been added.

Work out the moles of acid and salt in the initial buffer solution
Moles ethanoic acid= conc x vol = 0.200 x 0.500 = 0.100mol
Moles sodium ethanoate = conc x vol = 0.25 x 0.500 = 0.125mol

Work out the moles of acid and salt in buffer after the addition of 0.005mol NaOH
Moles ethanoic acid = 0.100 - 0.005 = 0.095 mol
Moles sodium ethanoate = 0.125 +0.005 = 0.130 mol

$$[H^+{}_{(aq)}] = Ka \frac{[CH_3COOH_{(aq)}]}{[CH_3COO^-{}_{(aq)}]}$$

We can enter moles of acid and salt straight into the equation as they both have the same new final volume

$$[H^+{}_{(aq)}] = 1.7 \times 10^{-5} \times \frac{0.095}{0.130} \rightarrow [H^+{}_{(aq)}] = 1.24 \times 10^{-5}$$

$$pH = -\log [H^+]$$
$$= -\log 1.24 \times 10^{-5}$$
$$= 4.91$$

Titration curves

Constructing a pH curve

1. Transfer 25cm^3 of acid to a conical flask with a volumetric pipette
2. Measure initial pH of the acid with a pH meter
3. Add alkali in small amounts (2cm^3) noting the volume added
4. Stir mixture to equalise the pH
5. Measure and record the pH to 1 d.p.
6. Repeat steps 3-5 but when approaching endpoint add in smaller volumes of alkali
7. Add until alkali in excess

Calibrate meter first by measuring known pH of a buffer solution. This is necessary because pH meters can lose accuracy on storage.
Most pH probes are calibrated by putting probe in a set buffer (often pH 4) and pressing a calibration button/setting for that pH. Sometimes this is repeated with a second buffer at a different pH

Can also improve accuracy by **maintaining** constant temperature

Strong acid – Strong base   e.g. HCl and NaOH
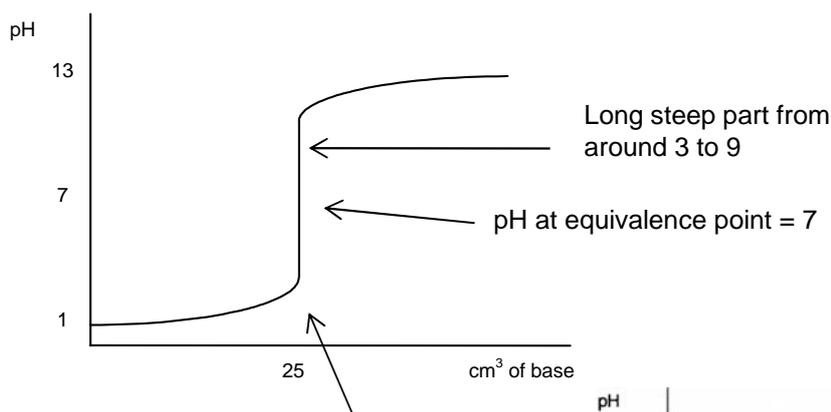

There are 4 main types of curve
1. Strong acid and strong base
2. Weak acid and strong base
3. Strong acid and weak base
4. Weak acid and weak base

Long steep part from around 3 to 9

pH at equivalence point = 7

You may also have to work out the neutralisation volume from titration data given in the question. These are done by standard titration calculations.

The Key points to sketching a curve:
Initial and final pH
Volume at neutralisation
General Shape (pH at neutralisation)

The equivalence point lies at the mid point of the extrapolated vertical portion of the curve.
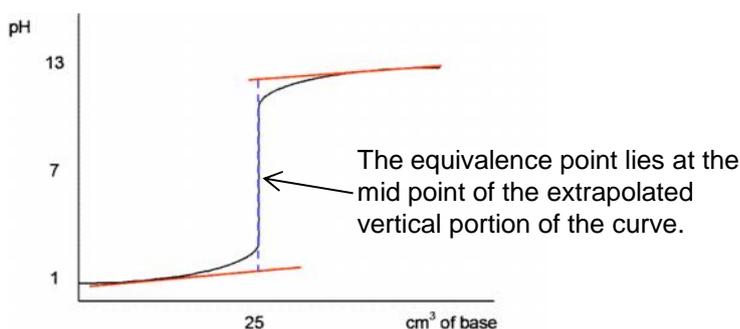

Weak acid – Strong base   e.g. CH$_3$CO$_2$H and NaOH

At the start the pH rises quickly and then levels off. The flattened part is called the buffer region and is formed because a buffer solution is made

Equivalence point >7

Steep part of curve >7 (around 7 to 9)

pH starts near 3
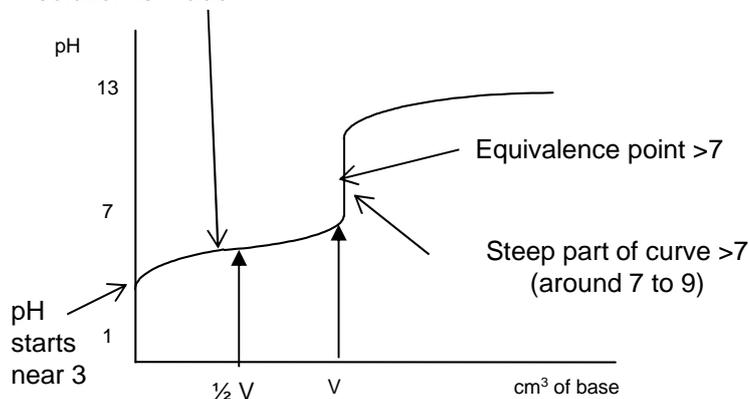

Half neutralisation volume

For weak acids

$$Ka= \frac{[H^+_{(aq)}][A^-_{(aq)}]}{[HA_{(aq)}]}$$

At ½ the neutralisation volume the [HA] = [A$^-$]

So Ka= [H$^+$] and pKa = pH

If we know the Ka we can then work out the pH at ½ V or vice versa.

If a pH curve is plotted then the pH of a weak acid at half neutralisation (½ V) will equal the pKa

8

Strong acid – Weak base

e.g. HCl and NH$_3$

Steep part of curve <7
(around 4 to 7)

Equivalence point < 7
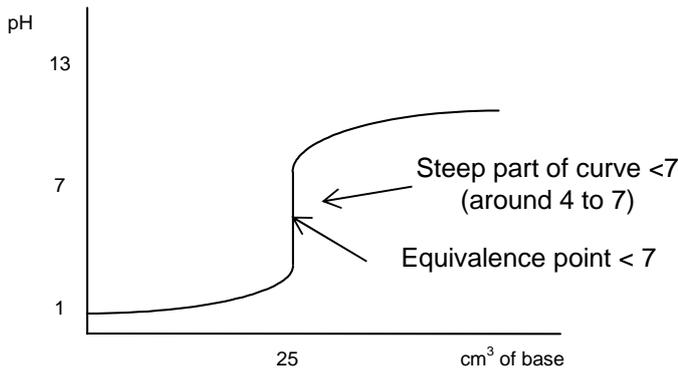

Weak acid – Weak base

e.g. CH$_3$CO$_2$H and NH$_3$

No Steep part of the curve
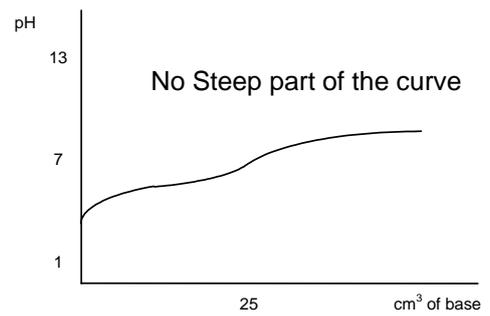

Choosing an Indicator

Indicators can be considered as weak acids. The acid must have a different colour to its conjugate base

An indicator changes colour from HIn to In$^-$ over a narrow range. Different indicators change colours over different ranges.

The end-point of a titration is defined as the point when the colour of the indicator changes colour

The end-point of a titration is reached when [HIn] = [In$^-$]. To choose a correct indicator for a titration one should pick an indicator whose end-point coincides with the equivalence point for the titration.

How indicators work

$HIn (aq) \rightleftharpoons In^-_{(aq)} + H^+_{(aq)}$
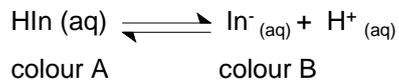

colour A   colour B

We can apply Le Chatelier to give us the colour.

In an acid solution the H$^+$ ions present will push this equilibrium towards the reactants. Therefore colour A is the acidic colour.

In an alkaline solution the OH$^-$ ions will react and remove H$^+$ ions causing the equilibrium to shift to the products. Colour B is the alkaline colour.

An indicator will work if the pH range of the indicator lies on the **steep** part of the titration curve. In this case the indicator will change colour rapidly and the colour change will correspond to the neutralisation point.

Only use phenolphthalein in titrations with strong bases but not weak bases-

Colour change: colourless acid → pink alkali

Use methyl orange with titrations with strong acids but not weak acids
Colour change: red acid → yellow alkali
(orange end point)

strong base

pH range for phenolphthalein

weak base

weak acid

pH range for methyl orange

strong acid
